Due to the increasing amount of natural disasters such as earthquakes and floods and unnatural disasters such as war and terrorist attacks, Humanitarian Relief Chain (HRC) is taken into consideration of most countries. Besides, this paper aims to contribute humanitarian relief chains under uncertainty. In this paper, we address a humanitarian logistics network design problem including local distribution centers (LDCs) and multiple central warehouses (CWs) and develop a scenario-based stochastic programming (SBSP) approach. Also, the uncertainty associated with demand and supply information as well as the availability of the transportation network's routes level after an earthquake are considered by employing stochastic optimization. While the proposed model attempts to minimize the total costs of the relief chain, it implicitly minimize the maximum travel time between each pair of facility and the demand point of the items. Additionally, a data set derived from a real disaster case study in the Iran area, and to solve the proposed model a exact method called ε-constraint in low dimension along with some well-known evolutionary algorithms are applied. Also, to achieve good performance, the parameters of these algorithms are tuned by using Taguchi method. In addition, the proposed algorithms are compared via four multi-objective metrics and statistically method. Based on the results, it was shown that: NSGA-II shows better performances in terms of SNS and CPU time, meanwhile, for NPS and MID, MRGA has better performances. Finally, some comments for future researches are suggested.

doi: 10.5829/ije.2017.30.10a.14

1. INTRODUCTION

In recent years, many areas around the world have been affected by natural disasters. These events are leading to the death, injury and destruction of property and disruption of daily activities that these unpleasant experiences are considered as natural disasters [1]. Moreover, disasters can be natural (such as earthquake, famine, tsunami, cyclone, hurricane, flood, etc.), manmade disasters (such as terrorism, war, civil disorder, etc.), disease (like HIV/aids or malaria) or extreme poverty situation.

The rate of natural disasters is increasing intensely due to population growth, global inclination in

urbanism, land use and stressing of ecosystems. From global perspective, the number of natural disasters is increasing every year. For example in 2005, there was 489 country-level disasters affecting 127 countries around the globe resulting in 104,698 people killed and 160 million people affected. According to Natural Disaster Database, earthquakes alone have killed more than 700,000 people in the past 20 years. Destructive effects of disasters, although inevitable, could be decreased by a proactive approach and the development of appropriate preparedness plans. Hence, necessity of appropriate measures to consider such disasters is needed extremely. Despite major contextual differences between commercial and humanitarian supply chains, in humanitarian operations, profit maximization which is the main objective in commercial supply chains is replaced by timely and appropriate provision of aid to

*Corresponding Author's Email: nijavadian@ustmb.ac.ir (N. Javadian)

beneficiaries. Besides, the high scale of these crises, has increased the need for efficient management of the relief supply chain.

Iran is one of the most disaster-prone country in the world due to its geographical conditions, that destructive earthquakes and the crisis which occurred after its occurrence, every year causing irreparable damage to people and the economy of the country. Existence of an integrated chain of all components and Humanitarian Relief, will be facilitate the disaster management in natural disasters, especially earthquakes that offered to the people involved in the events [2].

Humanitarian Relief Logistics is one of the most important elements of the relief operation in crisis management. Logistics planning in disaster relief are included sending of several items (such as medicine, rescue equipment, rescue teams, food, etc.) from a number of source of supply to multiple points of distribution in damaged areas through a chain structure. Also, the transfer of goods should be done quickly and efficiently so that the survival rate of affected people, and the cost of operations are maximized and minimized, respectively [3].

There are some review articles showing the state of the art in area of HRCs from various viewpoints consisting a general review on HRCs to identify suitable measures in various phases or steps of disasters which are pre-disaster, during-disaster and post-disaster [1, 4-6]. For instance, Caunhye et al. [6] reviewed proposed models for post and pre-disaster operations. In addition, they mentioned proposed models for traffic control and lifeline rehabilitation. More recently, Özdamar and Ertem [7] presented a survey that focused on the response and recovery planning steps of the disaster lifecycle.

Recently, a three-level relief chain model include suppliers, distribution centers, and affected areas is proposed by Zokaee et al. [2]. They proposed a MILP deterministic model by using stochastic optimization and they considered uncertainty for demand, supply, and all of the cost parameters, where the uncertain parameters are independent and bounded random variables. Their offered model attempts to minimize the total costs of the relief chain, it implicitly maximizes people's satisfaction level in the affected areas through applying a penalty to shortages of relief commodities. Moreover, a real disaster case study in the Iran for earthquakes is applied to test the efficiency of the suggested model. In addition, Sahebjamnia et al. [8] proposed a Hybrid Decision Support System (HDSS) include a simulator, a rule-based inference engine, and a knowledge-based system in order to design a three level HRC. Three main performance measures including the coverage, total cost, and response time are considered to make an explicit trade-off analysis between cost efficiency and responsiveness of the designed HRC. Also, a real case study in Tehran demonstrate use of stochastic data. Moreover, some researches paid attention to earthquake; for example, Yazdani and Kowsari, Nateghi et al., Rajabipour and Behnamfar and Yazdani et al. [9-12]. Finally, a brief review of papers in this research area is presented in Table 1.

TABLE 1. A brief review of related works

Papers	Objectives	Disaster type	Solution approach	Case study
Aksen and Aras [13]	Cost incurred before and after the interdiction attempt	General	Tabu search, Sequential solution method	Numerical experiments
Chang et al. [14]	Transportation, facility opening, equipment rental, penalties, shipping distance of rescue equipment	Flood	Sample average approximation	Taipei City
Chanta and Sangsawang [15]	Number of demand zones, Weight distance	Flood	Epsilon-constraint, Exact algorithm	Bangkruai, Thailand
Das and Hanaoka [16]	Cumulative cost of pre- and post-disaster circumstances	Earthquake	Exact algorithm	Bangladesh
Dekle et al. [17]	Facilities for each area with a given distance	General	Pick-the-Farthest Algorithm	Florida county
Dessouky et al. [18]	Demand-weighted distance	Epidemic	Exact algorithm	Anthrax disaster, Los Angeles
Feng and Wen [19]	Travel time, Number of private vehicle	Earthquakes	Genetic algorithm	Taiwan
Hong et al. [20]	Total logistic cost	General	Exact algorithm	South Carolina
Jabbarzadeh et al. [21]	Fixed cost and variable cost of facility, operational cost, transportation cost, inventory cost	Earthquakes	Branch and bound	Iran (IBTO)
Kedchaikulrat and Lohatepanont [22]	Cost structure and AHP score	General	Pareto dominance	Thai Red Cross

As is clear, some of these researches paid to disaster issues and tried to minimize total costs via exact method. Also, some of them used heuristic and meta-heuristic approaches and report the efficiency of these algorithms in their workes.

As one of this paper contribution, we consider two objective function include minimizing costs and minimizing maximum travel time which to the best of our knowledge simultaneous compination of them is not reported yet. Moreover, we developed two well-known meta-heuristics along with ε-constraint method to solve proposed framework which is another contribution of this paper. Additionally, a data set derived from a real disaster case study in the Iran area.

The structure of this paper is planned as follows: Section 2 and Section 3 presents the problem definition and model formulation, respectively. Section 4 presents Solution approach. In Section 5, parameter tuning process is performed. In Section 6, a computational results is presented. Finally, future research and conclusion are given in Section 7.

2. PROBLEM DESCRIPTION

The proposed network of disaster relief logistics is presented in Figure 1. The stages are the set of suppliers, the contain CWs and strategic stocks, and the last stage include of local distribution centers (LDCs) in the areas, which are affected by disaster. Hence, suppliers could play as a critical role in the relief chain and they prepare the required commodities to people in devastated areas. Those people could play a main role of the customers in the physical distribution. CWs contain warehouses, airports, train station and bus stations. The location of LDCs can be determined on the facilities of fortified existing public as health centers, schools, and mosques which are distributed in all over the city. Using of LDCs is completely justifiable since according to the response agency representatives it is not practical to found a large number of CWs that remain inactive until a disaster strikes.

Figure 1. Overall structure of HRC

3. MODEL FORMULATION

In this section, the model elements including indices, parameters, and variables are introduced as follows.

Indices

l	Index of potential suppliers
i	Index of potential *CWs*
j	Index of potential *LDCs*
k	Index of affected areas; demand points
h	Index of potential strategic stocks
m	Index of potential transportation mode
s	Index of potential disaster scenarios
q	Index of relief items
c	Index for storage capacity levels of CWs
g	Index of potential sub-sequent disasters

Parameters

F_i^c	Establishing cost of ith CW at capacity level c
G_j	Establishing cost of jth LDC
E_h	Establishing cost of hth strategic stocks
IH_q	Inventory holding cost of item q
UC_q^{is}	Unit inventory cost of unused item q at each CWs i in disaster scenario s
UL_q^{js}	Unit inventory cost of unused item q at each LDCs j in disaster scenario s
λ_{qs}^i	Usable inventory ratio of the qth item at the ith CW under scenario s
μ_{qs}^j	Usable inventory ratio of the qth item at the jth LDC under scenario s
ξ_l^s	Usable capacity ratio of the lth supplier under scenario s
US_q^s	Unit shortage cost of item q in disaster scenario s
TA_{ijm}^s	Transportation time between the ith CW and jth LDC via mode m to reflect the road and traffic conditions in disaster scenario s
TB_{lim}^s	Transportation time between the lth supplier and the ith CW via mode m to reflect the road and traffic conditions in disaster scenario s
ζ_{ijm}^s	1, if mode m is available under scenario s between the ith CW and jth LDC; 0 otherwise
ω_{lim}^s	1, if mode m is available under scenario s between the lth supplier and ith CW; 0 otherwise
D_{qk}^s	Demand level for the qth item at the kth demand point under scenario s
V^c	Storage capacity of each CW established at capacity level c
CA_j	Storage capacity of the jth LDC

SA_h^q	Storage capacity of the hth strategic stock for qth item
CS_{ql}	Storage capacity of the lth supplier for the qth item
CAP_{ijm}	Capacity of transportation mode between ith CW and jth LDC via mode m
ccp_{lim}	Capacity of transportation mode between the lth supplier and the ith CW via mode m
CT_{qlim}	Cost of transportation mode between the lth supplier and the ith CW via mode m for qth item
CTR_{qijkm}	Cost of transportation mode between ith CW and jth LDC to demand point k via mode m for qth item
A_q	Required unit storage capacity of the qth item
P_s	Probability of occurring the scenario s
ϕ_s^g	Sub-sequent disasters effects on demands after the major disaster in scenario s (g is the number of minor disaster in scenario s)
φ_s^g	Sub-sequent disasters effects on delivery time after major disaster scenario s (g is the number of minor disaster in scenario s)
ρ_{ql}	1, if supplier lth capable to deliver qth item

Decision variables

Y_i^c	1, if the ith candidate CW is opened at capacity level c; 0, otherwise
O_j	1, if the jth candidate LDC is opened; 0, otherwise
γ_h	1, if the hth candidate strategic stock is opened; 0, otherwise
τ_l	1, if the lth candidate supplier is selected; 0, otherwise
R_{qi}	Inventory level of the qth item at the ith CW
U_{qj}	Inventory level of the qth item at the jth LDC
UI_{qi}^s	Unused inventory level of the qth item at the ith CW under disaster scenario s
UR_{qj}^s	Unused inventory level of critical item q at the jth LDC under disaster scenario s
N_{ijm}^s	1, if transportation mode m is selected between ith CW and jth LDC under scenario s
C_{lim}^s	1, if transportation mode m is selected between lth supplier and ith CW under scenario s
x_{qjk}^s	Amount of the qth critical item to be delivered from the jth LDC to demand point k under disaster scenario s
z_{qijkm}^s	Amount of the qth item to be delivered from CW i to demand point k via jth LDC and transportation mode m under disaster scenario s
v_{qhjk}^s	Amount of the qth item to be delivered from strategic stock h to demand point k via jth LDC under disaster scenario s
w_{qlim}^s	Amount of the qth item to be delivered from supplier l to the ith CW via transportation mode m under

	disaster scenario s
η_{qk}^s	Amount of unfulfilled demand for the qth item in demand point k under disaster scenario s
T^{max}	Maximum travel time between each pair of facility and the demand point of the items

Assumptions
The main characteristics and assumptions used in the formulation of resilience HRC model are as follows:
- The capability of suppliers and candidate CWs may be partially disrupted by a disaster through damage to the roads and/or destruction to the facility. (Vulnerability of facilities is taken into account through incorporating different usable inventory ratio of each item at each CW/LDS under each scenario to capture supply uncertainty as a result of possible destruction of storage sites (completely or partially) during the disaster;
- Each CW is supplied by suppliers (with limited capacity).
- Each LDC is supplied by either CWs or multiple CWs or strategic stocks.
- Strategic stock is located in the safe places commonly outside of the expected disaster regions.
- Each strategic stock ships the items directly not to all the LDCs but nearest ones. (It means, there is the limitation of distance and each strategic stock can ship the items to the LDCs which are located at the acceptable distance far away from strategic stock.
- Transportation between suppliers and CWs or strategic stock and LDCs are considered to be multi-mode (Train, Plane, Helicopter, Truck, Motorcycle etc). The capability of each mode or rout may be partially disrupted by a disaster through damage to the roads. In fact, the possible destruction of transportation routes at different levels is considered.
- The resiliency level is calculated for each facility (i.e., suppliers, CWs, LDCs).
- The multiple disasters or sub-sequent minor disasters are considered for modeling. This study assumes that these minor disasters can affect the time of delivery and increasing the initial demand.
- More than one kind of relief commodity must be delivered, and each product is concerned with a various volume and a various cost of procurement, storage, and transportation.
- Each supplier and LDC can deliver a given number of relief commodities and it is based on suppliers' flexibility level.
- Inventory may be stored at CWs, LDCs and strategic stocks. Similar to suppliers, each CW, LDC and strategic stock can keep one or several kinds of relief commodity; consequently, they can deliver a given number of service and commodity.
- The parameters are uncertain (i.e., demand, cost, transportation time, etc.) and depend on various

factors including the disaster scenario and the impact of the disaster.

• Several capacity levels are considered for each candidate CW where appropriate capacity should be determined for each selected CW.

Here, we aim to present a bi-objective mixed integer linear programming to specify the location of CWs and LDCs, simultaneously and the corresponding inventory quantities for relief items, and the distribution quantities from supplier to CWs, from CWs to the affected areas (LDC) and from strategic stock to LDC.

Objective function (1) minimizes the total operating costs of selected CWs and LDCs, and their inventory costs. The last part of objective function (1), minimize total cost of unused inventories and shortage cost of unmet demands and transportation cost of items. Objective function (2) minimizes the maximum travel time between each pair of CW/LDC and demand point for the items.

Constraint (3) enforce restrictions on the available capacity of CWs. Constraint (4) implies that maximum number of CW with specified capacity level which could be constructed at each candidate site is one. Constraint (5) enforces restrictions on the available capacity of LDCs. Constraint (6) determines the unsatisfied demands for critical items. The right hand of Equation (6) determines initial demand plus demands added after sub-sequent minor disasters. Constraints (7) and (8) ensure that the distributed quantity of each item plus regarded unused inventory is equal to their corresponding inventory levels in respective CW/LDCs. Constraint (9) enforce restrictions on the available capacity of transportation system between pair of CW/LDCs. Constraint (10) enforces restrictions on the available capacity of suppliers. Each supplier can deliver a given number or set of critical items which is depend on suppliers' flexibility level. Also, each supplier may loss its capacity partially or totally and right hand of constraint (10) guarantees these conditions. Constraint (11) ensures restrictions on the available capacity of transportation system between pair of supplier/CWs. Constraint (12) enforce restrictions on the available capacity strategic stock. Constraints (13) and (14) calculate the maximum travel time. Constraints (15) and (16) ensure that the quantity of each item will be shipped if the transportation system is available. Constraints (17) and (18) determine the type of decision variables.

4. SOLUTION APPROACH

In low dimension problem, a exact method called ε-constraint is used and due to NP-*hardness* of the proposed model, exact methods are not proper for large-size problem. Besides, non-dominated sorting genetic algorithm (NSGA-II), non-dominated ranking genetic algorithm (NRGA) are applied to discover Pareto solutions. The mentioned algorithms are used in the same way in recent literature. Moreover, encoding and decoding procedures are illuminated in the following section.

4. 1. Encoding and Decoding Diverse methods have been established to encode the solutions in different models, such as: Michalewicz matrix, Prufer numbers, and priority-based technique. In this paper, the priority-based method is applied. To present the offered array or chromosome, a small-size example is shown in this sector to show the procedure of satisfying all the constraints by the suggested form. In this example, amounts of indices as $i=3$, $l=3$, $h=2$, $j=3$, $c=3$, $q=2$, and $k=2$ are assumed. The offered chromosome is a matrix with two rows for each items and $(l+2i+h+2j+k)$ columns which have three sectors. These sectors are considered according to the flows shown in Figure 1. The plan of suggested chromosome is shown in Figure 2.

The matrix shown in Figure 2 is randomly generated and all elements of first row of this matrix are set to random numbers in the interval [0, 1], and all elements of second row of this matrix are filled by uniform~ [1, c]. After sorting the values of first row and rounding the values of second row, the priority-based matrix is achieved. In addition, sorting of each segment, for each sub-segment, is done separately. The plan of suggested priority-based chromosome is shown in Figure 3.

Segment one presents the amount of shipped goods from suppliers (l) to CWs (i). Segment two presents the amount of shipped goods from CWs and strategic stocks ($h+i$) to LDCs (j). Also, segment three presents the amount of shipped goods from LDCs (j) to affected areas (k).

Moreover, Capacity level of each CWs (i) is presented in second row of proposed chromosome. Furthermore, allocation procedure is presented in Figure 4 which for each segment can be used from needed steps of it.

```
For s=1:S
For q=1:Q
Inputs:
I: set of source
J: set of applicant
D_js: demand of applicant j under scenario s
Ca_is: capacity of source i under scenario s
V(I+J): Encode solution of item q for scenario s
Outputs:
Xaloc_ijs: amount of shipment between nodes under scenario s
Y_j: binary variable shows the opened applicant
U_qis: amount of unused item q of source i under scenario s
U_qjs: amount of unused item q of applicant j under scenario s
While ∑_i Ca_is ≥ 0 && ∑_j D_js ≥ 0
Step1:  Xaloc_ijs = 0   ∀ i ∈ I, j ∈ J
Step2: select value of first column of sub-segment I for i
index
        select value of first column of sub-segment J for j
index
Step3: Xaloc_ijs = min(Ca_is , D_js)
        Update demands and capacities
        Ca_is = Ca_is - Xaloc_ijs        D_js = D_js - Xaloc_ijs
Step4: if Ca_is = 0 then V(1,I)=0
        if D_js = 0 then V(1,J)=0
End while
Step5:  U_qis = Ca_is      U_qjs = D_js
End for
Step6:  for j = 1 to J
        if ∑_s ∑_j Xaloc_ijs > 0 then Y_j=1
End for
End for
```

Figure 4. The allocation procedure

4. 2. NRGA and NSGA-II Usually, the real world issues and decisions are often complex, hence they cannot be solved by the exact methods in a proper time and cost [23, 24]. NSGA-II, offered by Deb et al. and NRGA, proposed by Al Jaddan et al., as two strong well-known multi-objective algorithms are utilized to evaluate the performance of solutions [25, 26]. The

chromosome structure and the function evaluation procedure in NSGA-II and NRGA algorithms are similar to each. The only difference between these algorithms is in their selection mechanism. NSGA-II uses binary tournament selection strategy while NRGA uses Roulette wheel selection strategy. Moreover, four types of mutation operators including reversion mutation, insertion mutation, continuous mutation, and swap mutation are used in local search sector of these algorithm. Furthermore, three types of crossover operators including single-point crossover, double-point crossover, and uniform crossover are utilized in these algorithms to enhance their performances. The main structure of these two algorithms is provided in literatures [25, 26].

4. 3. Performance Metrics
Four performance are used in this sector to evaluate the performance of the above-mentioned multi-objective evolutionary algorithms.

- Number of Pareto solution (NPS): The number of Pareto optimal solutions is offered by this metric. The more number of Pareto solutions in an algorithm is better performance.
- Mean ideal distance (MID): This metric is used to compute the distances between the Pareto fronts and the ideal point. The value of this metric is calculated by Equation (19) :

$$MID = \frac{\sum_{i=1}^{n} \sqrt{\left(\frac{f1_i - f1_{best}}{f1_{total}^{max} - f1_{total}^{min}}\right)^2 + \left(\frac{f2_i - f2_{best}}{f2_{total}^{max} - f2_{total}^{min}}\right)^2}}{n} \quad (19)$$

In this equation, n is the number of non-dominated solutions, and $f1_i$ and $f2_i$ are the value of ith non-dominated solution for each objective functions, respectively. ($f1_{best}$, $f2_{best}$) is the ideal point which characterizes the point (0,0) in this problem. ff_{total}^{max}, ff_{total}^{min} are the smallest and the biggest values of every fitness function among all non-dominated solutions resulted from an algorithm, respectively.

The less the value of MID, the better algorithm's performance.

- Spread of non-dominance solution (SNS): To assess the diversity of Pareto solutions, this metric is applied and is framed as Equation (20):

$$SNS = \sqrt{\frac{\sum_{i=1}^{n}(MID - C_i)^2}{n-1}} \quad (20)$$

Where, $C_i = \sqrt{f1_i^2 + f2_i^2}$

- Computational time (CPU time): The speed of running the algorithms to find near optimum solutions is one of the most important indices to evaluate the performance of an algorithm.

5. PARAMETERS SETTING

Here, the parameter tuning process is performed both on the parameters of the algorithms and on the model parameters in the following two subsections, respectively.

5. 1. Parameter Tuning
Here, in order to tuning the values of the algorithms' parameters, the Taguchi method is applied [27]. This effective method proposed by Taguchi and this method is utilized instead of the full factorial experimental design. Multi-objective algorithms are assessed according to multi-objective measures. Also, Equation (21) presents the selected response of Taguchi method in this study. The advantage of this response is that it considers both of the two main features of multi-objective algorithms entitled diversity and convergence.

$$MCOV = \frac{MID}{SNS} \quad (21)$$

The first step to produce a Taguchi design is identify the levels of each factors of algorithms. This step is shown in Table 2 where each factor has three levels. Then, by using Minitab ® software and applying the Taguchi method the L_9 orthogonal array for NRGA, NSGA-II algorithms are designated. The orthogonal arrays of each algorithm along with the achieved results are displayed in Table 3.

For each algorithm, the related S/N ratio chart obtained by the Minitab® software is shown in Figure 5-6. In this figure, the best level of each factor is selected to be the one with the highest S/N ratio. Besides, {Pc=0.7, Pm=0.1, N-pop=100, Max-iteration =100} are the selected parameters for NSGA-II and {Pc=0.7, Pm=0.15, N-pop=50, Max-iteration =200} are the selected parameters for NRGA by using the Figures 5 and 6.

Moreover, it should be notice that the Taguchi experiment is perform for the first test problem of Table 4 and for other test problems these tuned parameters are utilized.

TABLE 2. Algorithm parameter ranges along with their levels

Algorithms	parameters	Parameter level		
		Level 1	Level 2	Level 3
NSGA-II	Pc	0.7	0.8	0.9
	Pm	0.05	0.1	0.15
	N-pop	50	100	150
	Max-iteration	100	200	300
NRGA	Pc	0.7	0.8	0.9
	Pm	0.05	0.1	0.15
	N-pop	50	100	150
	Max-iteration	100	200	300

TABLE 3. The orthogonal array L9 and results for the algorithms

| Run	Pc	Pm	N_{pop}	Max-iter	NRGA	NSGA-II
1	1	1	1	1	1.5426e-011	1.7548e-011

Figure 6. Signal to noise plot of NRGA

Also, in performing of Taguchi experiment, the "smallest response is better" as a selected response for identifying of parameters is used.

5. 2. Case Study   In this section, to accumulation of the proposed model's parameters, a case study in Iran is applied. In this respect, the proposed model is applied on the case study to demonstrate the correctness and appropriateness of the results. In fact, this research is stimulated regarding to the complex issue of designing a HRC in Mazandaran province in Iran. Accordingly, we provide details of the case study for the design of HRC

in one of the northern province of Iran, Mazandaran; aiming at better response to a potential disasters. The province covers a region of 23,842 km². In addition, Mazandaran is one of the most thickly populated provinces in Iran and has various natural resources, especially large reservoirs of oil and natural gas. The population of the province was 2,922,432 regarding to the census of 2006, in which 46.82% villagers, 53.18% were urban dwellers, and remaining were non-residents.

Increasing the number of disruption scenarios represented that the leads to computational time could be increased. Meanwhile, the number of scenarios which is considered for the network design problems is 3 disruption scenarios in our case study.

The level of a disaster scenario depends on the occurrence time which are separately presented in the Table 4. The proposed mathematical model is coded in the MATLAB^{TM} 2010 software and regarding to a Pentium dual-core 2.5 GHz computer with 4 GB RAM is solved. Moreovere, other parameters of proposed model such as: the general data of the test problems and other parameters are presented in Tables 5-7.

6. COMPUTATIONAL RESULTS

In this sector, the performances of the offered tuned multi-objective algorithms are evaluated and compared using the multi-objective metrics given in Section 4.3. Table 8 contains the computational results of employing

the algorithms on the 10 test problems introduced in Section 5.2. To validate proposed approaches, ε-constraint method is used in low dimension problems. As is clear, two developed metaheuristics have a near behavior with ε-constraint method which it refers to efficiency of them.

In order to compare the obtained metrics, analysis of variance (ANOVA) is used. The results prove that there is a clear statistically significant difference between performances of the algorithms. The intervals plot (at the 95% confidence level) for these algorithms for each metric are shown in Figures 7-10. Each interval plot has three points for each algorithm in each metric.

TABLE 8. The obtained results of algorithms

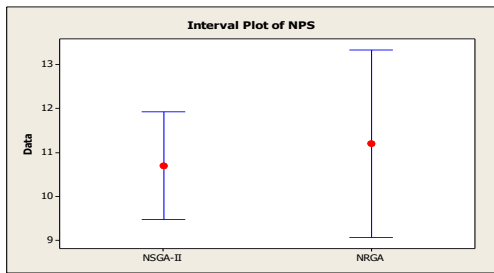

Figure 7. The intervals plot of NPS

Figure 10. The intervals plot of SNS
Figure 8. The intervals plot of CPU Time

We note that while in terms of the SNS and NPS metrics, bigger values are desired, for spacing, MID and CPU time, smaller values are better. Then, in general, based on the outputs in the last row of Table 8, it is clear that NSGA-II shows better performances in terms of SNS and CPU time. Meanwhile, for other two metrics, NPS and MID, MRGA has better performances. Besides, to clarify better performance of the proposed Pareto-based algorithms, the obtained Pareto solutions of all algorithms on four test problem 1, 5, and 9 are presented in Figures 11-13.

7. CONCLUSION

In this paper, a bi-objective mixed integer linear programming to specify the location of CWs and LDCs, simultaneously and the corresponding inventory quantities for relief items, and the distribution quantities from supplier to CWs, from CWs to the affected areas (LDC) and from strategic stock to LDC. The presented model seeks to minimize the cost variability, expected total cost. In the second stage, a relief distribution plan is extended based on different disaster scenarios by goals of minimizing the total distribution time, the maximum weighted distribution time of critical items, total cost of unused inventories, and the shortage cost of unmet demands. The model considers uncertainty in the locations where the demands might increase like as the possibility that some of the pre-arranged supplies at CWs or suppliers might be destroyed partially regarding to the disaster (i.e., supply uncertainty). To demonstrate the imprecise parameters, we make utilize of discrete scenarios from set S of potential disaster conditions. Then, in view of the NP-Hardness of proposed model, two tuned Pareto-based multi-objective meta-heuristic algorithms, called NSGA-II and NRGA were proposed to solve the problem.

Moreover, to achieve better performance, these algorithms are tuned by Taguchi method. The proposed algorithms were compared using 10 test problems via four multi-objective metrics. Also, to validate proposed framework, ε-constraint method is used in low dimension problems. Moreover, the perfomance of two algorithms for each   matric via statistically method

called the intervals plot are analyzed. As is shown in Figure 11 and Table 8, two developed metaheuristics have a close behavior with ε-constraint method which refers to efficiency of these two algorithms. Finally, based on the results it was shown that: NSGA-II shows better performances in terms of SNS and CPU time, meanwhile, for NPS and MID, MRGA has better performances. Finaly, managers by using this comprehensive framework and solution approaches can achive the best performance includes minimum total costs and minimum of maximum travel time, and based on their organization directions can choose best solution among pareto fronts. As a limitation, it should be noted that the proposed framework and data are related to the selected case study and we cannot be sure that these outcomes will be efficient for other areas.

As future research, the model can be extended to have multiple fuzzy-objective. In addition, different methods for solving the proposed model can be developed. Applying the proposed model in similar fields can be one of the research areas for the future studies. The proposed solution approaches can also be used for the aforementioned cases.

چکیده

با توجه به افزایش میزان بلایای طبیعی مانند زلزله و سیل و بلایای غیر طبیعی مانند جنگ و حملات تروریستی، موضوع زنجیره امدادی بشردوستانه مورد نظر بسیاری از کشورها قرار گرفته است. بنابراین، هدف این مقاله کمک به زنجیره امدادی بشر دوستانه تحت عدم قطعیت می باشد. در این پژوهش، یک مساله طراحی شبکه لجستیک بشردوستانه شامل مراکز توزیع محلی (LDC) و انبارهای مرکزی متعدد (CWS) و توسعه یک رویکرد تصادفی مبتنی بر سناریو (SBSP) ارائه شده است. همچنین، عدم قطعیت در ارتباط با تقاضا و اطلاعات تامین و نیز در دسترس بودن سطوح مسیرهای شبکه حمل و نقل بعد از زلزله با ارائه بهینه سازی غیرقطعی در نظر گرفته شده است. اهداف مدل ارائه شده تلاش برای به حداقل رساندن کل هزینه های زنجیره امداد و ضمنا به حداقل رساندن حداکثر زمان مسیر بین هر جفت از امکانات و نقاط تقاضا است. علاوه بر این، یک مجموعه داده حاصل از یک مطالعه موردی فاجعه واقعی در ایران استفاده شده است و برای حل مدل پیشنهادی برخی از الگوریتم های تکاملی شناخته شده به همراه روش اپسیلن محدودیت در ابعاد کوچک استفاده می شوند. همچنین برای دستیابی به عملکرد بهتر، پارامترهای الگوریتم ها با استفاده از روش تاگوچی تنظیم شده اند. همچنین الگوریتم های پیشنهادی نسبت به سنجه های استاندارد چند هدفه مقایسه شده اند، که از لحاظ شاخص های SNS و زمان الگوریتم NSGA-II عملکرد بهتری داشته است و از لحاظ شاخص های MID و تعداد نقاط پارتو الگوریتم NRGA بهتر بوده است. در نهایت پیشنهاداتی برای تحقیقات آتی ارائه شده است.
